

Manipulating and Formatting the Data in Your Program

Objectives

After completing this lesson, you should be able to:

- Describe the `String` class and use some of the methods of the `String` class
- Use the JDK documentation to search for and learn how to use a class
- Describe the `StringBuilder` class
- Explain what a constant is and how to use it
- Explain the difference between promoting and casting of variables

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

String Class

```
String hisName = "Fred Smith"; — Standard syntax
```

The `new` keyword can be used,
but it is *not* best practice:

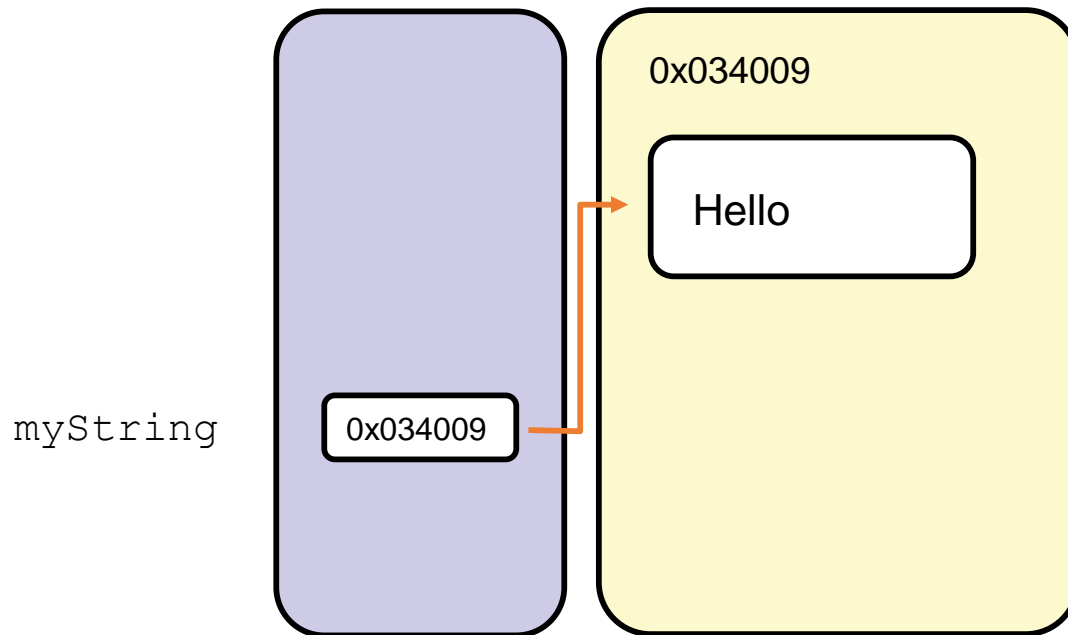

↓

```
String herName = new String("Anne Smith");
```

- A `String` object is immutable; its value cannot be changed.
- A `String` object can be used with the string concatenation operator symbol (+) for concatenation.

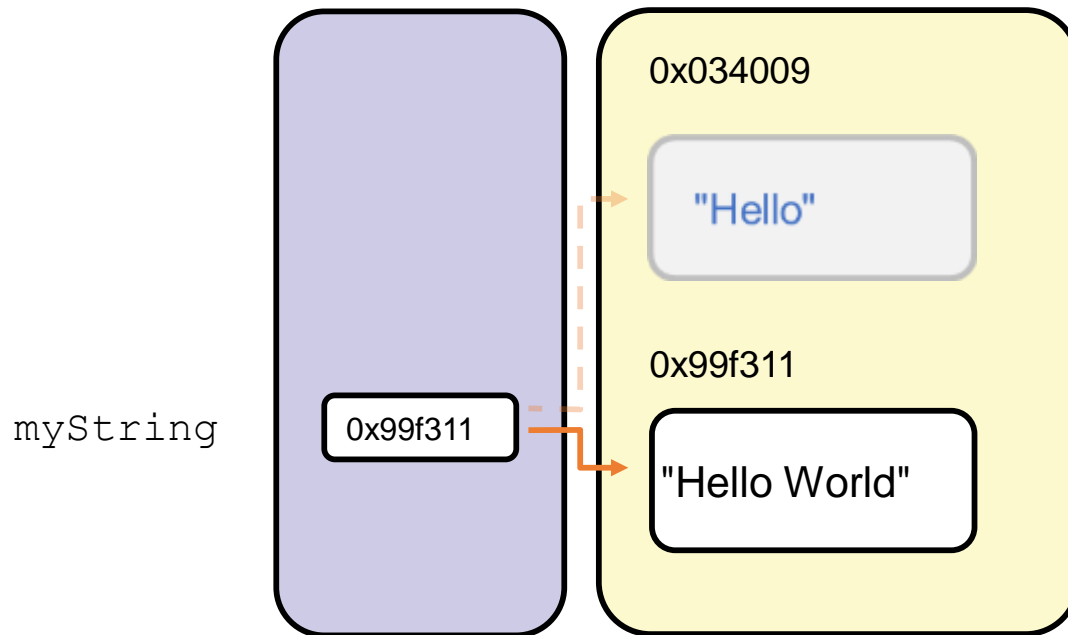

Concatenating Strings

```
String myString = "Hello";
```

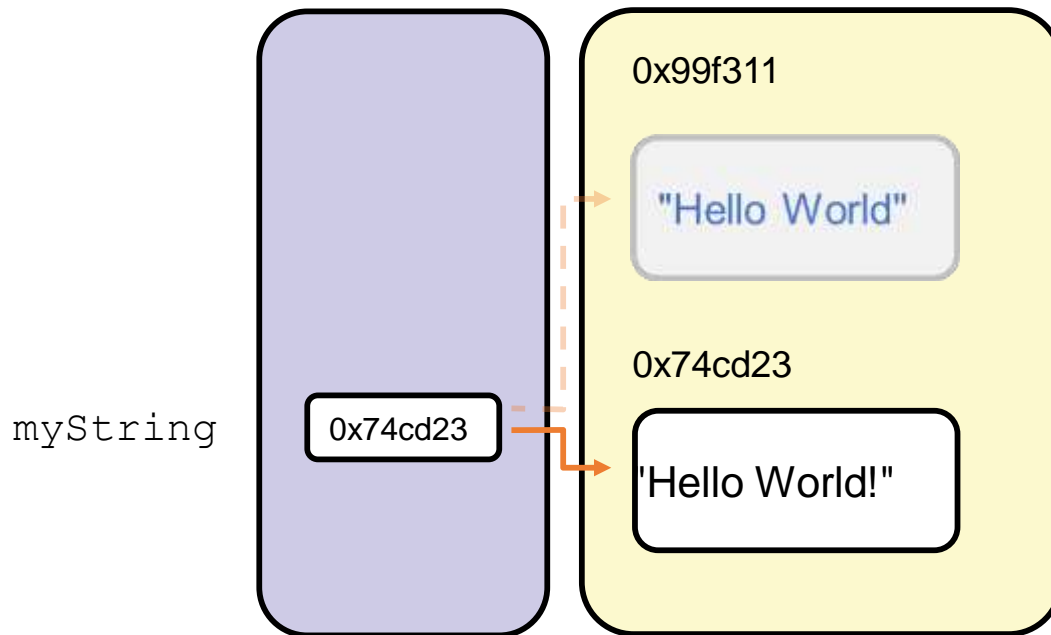

Concatenating Strings

```
String myString = "Hello";  
myString = myString.concat(" World");
```

Concatenating Strings

```
String myString = "Hello";  
myString = myString.concat(" World");  
myString = myString + "!"
```

String Method Calls with Primitive Return Values

A method call can return a single value of any type.

- An example of a method of primitive type `int`:

```
String hello = "Hello World";  
int stringLength = hello.length();
```

String Method Calls with Object Return Values

Method calls returning objects:

```
String greet = " HOW ".trim();
```

```
String lc = greet + "DY".toLowerCase();
```

Or

```
String lc = (greet + "DY").toLowerCase();
```

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

Java API Documentation

Consists of a set of webpages;

- Lists all the classes in the API
 - Descriptions of what the class does
 - List of constructors, methods, and fields for the class
- Highly hyperlinked to show the interconnections between classes and to facilitate lookup
- Available on the Oracle website at:
<http://download.oracle.com/javase/8/docs/api/index.html>

Java Platform SE 8 Documentation

Select All Classes
or a particular
package.

Details about the
class selected

The classes for the
selected
package(s) are
listed here.

The screenshot displays the Java Platform SE 8 Documentation website. On the left, a sidebar contains a search bar and a list of packages under the heading 'Packages'. The 'java.lang' package is selected, and a list of classes is shown below it, including 'String', 'StringBuffer', 'StringBuilder', 'System', 'Thread', 'ThreadGroup', 'ThreadLocal', 'Throwable', and 'Void'. The 'String' class is highlighted. On the right, the main content area shows the details for the 'String' class. It includes a navigation bar with tabs for 'Overview', 'Package', 'Class' (selected), 'Use', 'Tree', 'Deprecated', 'Index', and 'Help'. Below the navigation bar, there are links for 'Prev Class', 'Next Class', 'Frames', and 'No Frames'. The class details section shows the package 'java.lang', the class name 'String', and its inheritance hierarchy: 'java.lang.Object' and 'java.lang.String'. It also lists 'All Implemented Interfaces: Serializable, CharSequence, Comparable<String>'. The class declaration is shown as 'public final class String extends Object implements Serializable, Comparable<String>, CharSequence'. A description at the bottom states: 'The String class represents character strings. All string literals in Java programs, such as "abc", are implemented as instances of this class.'

Java Platform SE 8: Method Summary

```
public int charAt(String str)
```

The return type
of the method

The name
of the
method

The type of the parameter that must
be passed into the method

Method Summary

Methods

Modifier and Type	Method and Description
char	charAt (int index) Returns the char value at the specified index.
int	codePointAt (int index) Returns the character (Unicode code point) at the specified index.
int	codePointBefore (int index) Returns the character (Unicode code point) before the specified index.
int	codePointCount (int beginIndex, int endIndex) Returns the number of Unicode code points in the specified text range of this String.
int	compareTo (String anotherString) Compares two strings lexicographically.
int	compareToIgnoreCase (String str) Compares two strings lexicographically, ignoring case differences.
String	concat (String str) Concatenates the specified string to the end of this string.

Java Platform SE 8: Method Detail

Click here to get the detailed description of the method.

int	indexOf (String str)	Returns the index within this string of the first occurrence of the specified substring.
int	indexOf (String str, int fromIndex)	Returns the index within this string of the first occurrence of the specified substring, starting at the specified index.

Detailed description for the
indexOf() method

Further details about
parameters and return value
are shown in the method list.

indexOf
<pre>public int indexOf(String str)</pre>
Returns the index within this string of the first occurrence of the specified substring.
The returned index is the smallest value <i>k</i> for which:
<pre> this.startsWith(str, k)</pre>
If no such value of <i>k</i> exists, then -1 is returned.
Parameters:
str - the substring to search for.
Returns:
the index of the first occurrence of the specified substring, or -1 if there is no such occurrence.

indexOf Method Example

```
1 String phoneNum = "404-543-2345";
2 int idx1 = phoneNum.indexOf('-');
3 System.out.println("index of first dash: "+ idx1);
4
5
6 int idx2 = phoneNum.indexOf('-', idx1+1);
7 System.out.println("second dash idx: "+idx2);
```

The 1-arg version

The 2-arg version

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- **Doing more with primitive data types**
- Using the remaining numeric operators
- Promoting and casting variables

Primitive Data Types

- Integral types (`byte`, `short`, `int`, and `long`)
- Floating point types (`float` and `double`)
- Textual type (`char`)
- Logical type (`boolean`)

Some New Integral Primitive Types

Type	Length	Range
<code>byte</code>	8 bits	-2^7 to $2^7 - 1$ (-128 to 127, or 256 possible values)
<code>short</code>	16 bits	-2^{15} to $2^{15} - 1$ (-32,768 to 32,767, or 65,535 possible values)
<code>int</code>	32 bits	-2^{31} to $2^{31} - 1$ (-2,147,483,648 to 2,147,483,647, or 4,294,967,296 possible values)
<code>long</code>	64 bits	-2^{63} to $2^{63} - 1$ (-9,223,372,036,854,775,808 to 9,223,372,036,854,775,807, or 18,446,744,073,709,551,616 possible values)

Floating Point Primitive Types

Type	Float Length
<code>float</code>	32 bits
<code>double</code> (default type for floating point literals)	64 bits

Example:

```
public float pi = 3.141592F;
```

Textual Primitive Type

- The only primitive textual data type is `char`.
- It is used for a single character (16 bits).
- Example:

```
- public char colorCode = 'U';
```

||

Single quotes must be used with char literal values.

Java Language Trivia: Unicode

- Unicode is a standard character encoding system.
 - It uses a 16-bit character set.
 - It can store all the necessary characters from most languages.
 - Programs can be written so they display the correct language for most countries.

Character	UTF-16	UTF-8	UCS-2
A	0041	41	0041
c	0063	63	0063
Ö	00F6	C3 B6	00F6
𐄎	4E9C	E4 BA 9C	4E9C
♫	D834 DD1E	F0 9D 84 9E	N/A

Constants

- Variable (can change):

- `double salesTax = 6.25;`

- Constant (cannot change):

- `final int NUMBER_OF_MONTHS = 12;`

The `final` keyword
causes a variable to be
read only.

Quiz

The variable declaration `public int myInteger=10;` adheres to the variable declaration and initialization syntax.

- a. True
- b. False

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

Modulus Operator

Purpose	Operator	Example	Comments
Remainder	$\%$ modulus	<pre>num1 = 31; num2 = 6; mod = num1 % num2; mod is 1</pre>	<p>Remainder finds the remainder of the first number divided by the second number.</p> <div><div>5 R</div><div>6 31</div><div>30</div><div>1</div></div> <p>Remainder always gives an answer with the same sign as the first operand.</p>

Combining Operators to Make Assignments

Purpose	Operator	Examples <code>int a = 6, b = 2;</code>	Result
Add to and assign	<code>+=</code>	<code>a += b</code>	<code>a = 8</code>
Subtract from and assign	<code>-=</code>	<code>a -= b</code>	<code>a = 4</code>
Multiply by and assign	<code>*=</code>	<code>a *= b</code>	<code>a = 12</code>
Divide by and assign	<code>/=</code>	<code>a /= b</code>	<code>a = 3</code>
Get remainder and assign	<code>%=</code>	<code>a %= b</code>	<code>a = 0</code>

More on Increment and Decrement Operators

Operator	Purpose	Example
++	Preincrement (++ <i>variable</i>)	<pre>int id = 6; int newId = ++id; id is 7, newId is 7</pre>
	Postincrement (<i>variable</i> ++)	<pre>int id = 6; int newId = id++; id is 7, newId is 6</pre>
--	Predecrement (-- <i>variable</i>)	<i>(same principle applies)</i>
	Postdecrement (<i>variable</i> --)	

Increment and Decrement Operators (++ and --)

Examples:

```
1  int count=15;
2  int a, b, c, d;
3  a = count++;
4  b = count;
5  c = ++count;
6  d = count;
7  System.out.println(a + ", " + b + ", " + c + ", " + d);
```

Output:

15, 16, 17, 17

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

Promotion

- Automatic promotions:
 - If you assign a smaller type to a larger type

- Examples of automatic promotions:

- `long intToLong = 36;`
- `double intToDouble = 3;`

Caution with Promotion

Equation:

$$55555 * 66666 = 3703629630$$

Example of potential issue:

```
1 int num1 = 55555;  
2 int num2 = 66666;  
3 long num3;  
4 num3 = num1 * num2;           //num3 is -591337666
```

Example of potential solution:

```
1 int num1 = 55555;  
2 long num2 = 66666; ——— Changed from int to long  
3 long num3;  
4 num3 = num1 * num2;           //num3 is 3703629630
```

Caution with Promotion

Equation:

$$7 / 2 = 3.5$$

Example of potential issue:

```
1 int num1 = 7;  
2 int num2 = 2;  
3 double num3;  
4 num3 = num1 / num2;           //num3 is 3.0
```

Example of potential solution:

```
1 int num1 = 7;  
2 double num2 = 2; ——— Changed from int to double  
3 double num3;  
4 num3 = num1 / num2;           //num3 is 3.5
```

Type Casting

- When to cast:
 - If you assign a larger type to a smaller type

- Examples of casting:

- `int longToInt = (int)20L;`
- `short doubleToShort = (short)3.0;`

Caution with Type Casting

Example of potential issue:

```
1 int myInt;  
2 long myLong = 123987654321L;  
3 myInt = (int) (myLong); // Number is "chopped"  
4  
// myInt is -566397263
```

Safer example of casting:

```
1 int myInt;  
2 long myLong = 99L;  
3 myInt = (int) (myLong); // No data loss, only zeroes.  
4  
// myInt is 99
```

Caution with Type Casting

- Be aware of the possibility of lost precision.

Example of potential issue:

```
1 int myInt;  
2 double myPercent = 51.9;  
3 myInt = (int) (myPercent); // Number is "chopped"  
4  
// myInt is 51
```

Using Promotion and Casting

Example of potential issue:

```
1 int num1 = 53; // 32 bits of memory to hold the value
2 int num2 = 47; // 32 bits of memory to hold the value
3 byte num3;           // 8 bits of memory reserved
4 num3 = (num1 + num2); // causes compiler error
```

Solution using a larger type for num3:

```
1 int num1 = 53;
2 int num2 = 47;
3 int num3; ————— Changed from byte to int
4 num3 = (num1 + num2);
```

Solution using casting:

```
1 int num1 = 53; // 32 bits of memory to hold the value
2 int num2 = 47; // 32 bits of memory to hold the value
3 byte num3;           // 8 bits of memory reserved
4 num3 = (byte)(num1 + num2); // no data loss
```

Compiler Assumptions for Integral and Floating Point Data Types

- Most operations result in an `int` or `long`:
 - `byte`, `char`, and `short` values are automatically promoted to `int` prior to an operation.
 - If an expression contains a `long`, the entire expression is promoted to `long`.
- If an expression contains a floating point, the entire expression is promoted to a floating point.
- All literal floating point values are viewed as `double`.

Automatic Promotion

Example of potential problem:

```
short a, b, c;  
a = 1 ;  
b = 2 ;  
c = a + b; //compiler error
```

a and b are automatically promoted to integers.

Example of potential solutions:

- Declare `c` as an `int` type in the original declaration:

```
int c;
```

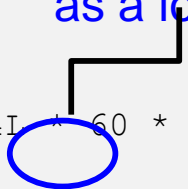

- Type cast the `(a+b)` result in the assignment line:

```
c = (short) (a+b);
```

Using a long

```
1 public class Person {
2
3     public int ageYears = 32;
4
5     public void calculateAge() {
6
7         int ageDays = ageYears * 365;
7         long ageSeconds = ageYears * 365 * 24 * 60 * 60;
8
9         System.out.println("You are " + ageDays + " days old.");
10        System.out.println("You are " + ageSeconds + " seconds old.");
11
12    } // end of calculateAge method
13 } // end of class
```

Using the L to indicate a long
will result in the compiler
recognizing the total result
as a long.

Using Floating Points

Example of potential problem:

```
int num1 = 1 + 2 + 3 + 4.0;  
//compiler error
```

```
int num2 = (1 + 2 + 3 + 4) * 1.0;
```

Expressions are automatically promoted to floating points.

```
//compiler error
```

Example of potential solutions:

- **Declare num1 and num2 as double types:**

```
double num1 = 1 + 2 + 3 +  
4.0; //10.0
```

```
double num2 = (1 + 2 + 3 + 4) * 1.0;  
//10.0
```

- **Type cast num1 and num2 as int types in the assignment line:**

```
int num1 = (int) (1 + 2 + 3 +  
4.0); //10
```

```
int num2 = (int) ((1 + 2 + 3 + 4) * 1.0); //10
```

Floating Point Data Types and Assignment

- Example of potential problem:

```
float float1 = 27.9; //compiler error
```

- Example of potential solutions:

- The F notifies the compiler that 27.9 is a float value:

```
float float1 = 27.9F;
```

- 27.9 is cast to a float type:

```
float float1 = (float) 27.9;
```

Quiz

Which statements are true?

- a. There are eight primitive types built in to the Java programming language.
- b. `byte`, `short`, `char`, and `long` are the four integral primitive data types in the Java programming language.
- c. A boolean type variable holds `true`, `false`, and `nil`.
- d. `short Long = 10;` is a valid statement that adheres to the variable declaration and initialization syntax.

Summary

In this lesson, you should have learned how to:

- Describe the `String` class and use some of the methods of the `String` class
- Use the JDK documentation to search for and learn how to use a class
- Use the `StringBuilder` class to manipulate string data
- Create a constant by using the `final` keyword in the variable declaration
- Describe how the Java compiler can use promotion or casting to interpret expressions and avoid a compiler error
